Abstract
Background: This study was conducted to evaluate the effects of probiotic supplementation on gene expression related to inflammation, insulin, and lipid in patients with Parkinson’s disease (PD).

Methods: This randomized, double-blind, placebo-controlled clinical trial was conducted in 50 patients with PD as a pilot study. Participants were randomly allocated into two groups to take either 8×10^8 CFU/day probiotic supplements or placebo (n = 25 each group, one capsule daily) for 12 weeks. Gene expression related to inflammation, insulin, and lipid was quantified in peripheral blood mononuclear cells (PBMC) of PD patients, with RT-PCR method.

Results: After the 12-week intervention, compared with the placebo, probiotic intake downregulated gene expression of interleukin-1 (IL-1) (P = 0.03), IL-8 (P < 0.001) and tumor necrosis factor alpha (TNF-α) (P = 0.04) in PBMC of subjects with PD. In addition, probiotic supplementation upregulated transforming growth factor beta (TGF-β) (P = 0.02) and peroxisome proliferator-activated receptor gamma (PPAR-γ) (P = 0.03) in PBMC of subjects with PD compared with the placebo. We did not observe any significant effect of probiotic intake on gene expression of low-density lipoprotein receptor (LDLR) and vascular endothelial growth factor (VEGF) in PBMC of patients with PD.

Conclusion: Overall, probiotics supplementation for 12 weeks in PD patients significantly improved gene expression of IL-1, IL-8, TNF-α, TGF-β and PPAR-γ, but did not affect gene expression of VEGF and LDLR, and biomarkers of inflammation and oxidative stress.

Keywords: Inflammation, insulin metabolism, Parkinson’s disease, probiotics supplementation

Introduction
Parkinson’s disease (PD) is a disabling pathology that has a usually asymmetric onset, and is characterized by both motor and non-motor symptoms which affects millions of people worldwide. Experimental models of PD proposed that the loss of dopaminergic neurons is extremely due to increased inflammatory cytokines especially tumor necrosis factor alpha (TNF-α). Furthermore, the modulation of peroxisome proliferator-activated receptor gamma (PPAR-γ) activity results in neuroprotective impacts on biomarkers of oxidative stress, apoptosis, and neuroinflammation in PD. On the other hand, dyslipidemia and obesity are well-established risk factors for cognitive disturbances and dementia in older adults.

Epidemiological and experimental studies in human and animal models support a general schema which implicates the gut microbiota through the microbiome-gut-brain axis in the pathogenesis of common neurodegenerative diseases, including PD and Alzheimer’s disease. In addition, depletion or modulation of the gut microbiota can influence the severity of the central pathology or behavioral deficits observed in brain disorders. Some studies have previously reported the beneficial effects of probiotics on metabolic and genetic diseases related to neurodegenerative disorders. Previously, we showed that 12 weeks of probiotic administration in people with multiple sclerosis (MS) significantly decreased...
Subjects and Methods

Participants
This randomized, double-blind, placebo-controlled clinical trial, registered in the Iranian Registry of Clinical Trials (identifier: IRCT20170513033941N34; http://www.irct.ir), was conducted among population with PD, aged 50–80 years old, diagnosed according to the clinical diagnostic criteria of the UK PD Society Brain Bank and referred to the Shahid Beheshti hospital in Kashan, Iran, between October 2017 and January 2018. This study was performed according to Good Clinical Practice guidelines, and the study protocol was approved by the Research Ethics Committee of Islamic Azad University. Written informed consent was obtained from all patients before the study. Exclusion criteria were as following: taking probiotic and/or symbiotic supplements, taking antioxidant supplements and anti-inflammatory agents, suffering from depression and severe psychosis, hypothyroidism, hyperthyroidism, and being smoker.

Study Design
At baseline, to decrease potential confounding effects, all participants were stratified randomly according to age, body mass index (BMI), gender and the dosage and kind of medications. Then, subjects in each block were randomly allocated into 2 treatment groups to take either $8 \times 10^9$ CFU/day probiotic, containing *Lactobacillus acidophilus*, *Bifidobacterium bifidum*, *L. reuteri*, and *Lactobacillus fermentum* (each $2 \times 10^9$) (n = 25) or placebo (n = 25) for 12 weeks. In addition, all participants were matched according to age, BMI, gender, and the dosage and type of medications. Probiotics and placebos were produced by Lactocare Zisttakhmir Company (Tehran, Iran) and Barij Essence Pharmaceutical Company (Kashan, Iran), respectively. Since the supplements and placebo capsules had similar packaging, patients and researchers were unaware of the content of the package until the end of study. Randomization assignment was done using computer-generated random numbers as blindness by a trained staff at the neurology clinic. Patients, investigators, clinical site staff and laboratory staff were all masked to treatment assignment throughout the study. All people completed 3-d dietary records (2 weeks’ days and one weekend day) at weeks 1, 5, 9, and 12 of the trial. To obtain nutrient intakes of participants according to 3-d food records, we applied Nutritionist IV software (First Databank, San Bruno, CA) adapted for the Iranian food pattern. Physical activity was described as metabolic equivalents (METs) in hours per day. To determine the METs for each subject, we multiplied the times (in hour per day) reported for each physical activity by its related METs coefficient by standard tables.

Treatment Adherence
Compliance was evaluated by counting the remaining supplements and placebos, and subtracting from the number of supplements provided to the participants. To increase compliance rate, all subjects received reminder messages on their cell phones every day to remind them to take their capsules.

Assessment of Anthropometric Parameters
Weight was measured on a balance scale (Seca, Hamburg, Germany) at baseline and after the 12-week intervention in the clinic by a trained staff member. Height was determined by a non-stretched tape measure (Seca, Hamburg, Germany) to the nearest 0.1 cm. BMI was determined as weight in kg divided by height in meters squared.

Assessment of Outcomes
The primary outcome was gene expression related to inflammatory markers. The secondary outcome was gene expression related to insulin and lipid metabolism, and biomarkers of inflammation and oxidative stress.

Biochemical Measurements
The nitric oxide (NO) levels were assessed using Griess method with inter- and intra-assay coefficient variances (CVs) of lower than 5%. Plasma glutathione (GSH) was measured using Beutler et al method with inter- and intra-assay CVs less than 5%.
Isolation of Lymphocyte, RNA Extraction and cDNA Synthesis

Twenty milliliters of blood samples were collected in anti-coagulant EDTA tubes. Lymphocytes were isolated using 50% percoll solution (Sigma-Aldrich, Dorset, UK) gradient by centrifugation for 20 minutes and 3000 rpm at 4°C. Total RNA was extracted based on acid guanidinium-phenol-chloroform procedure using RNX™-plus reagent (Cinnacolon, Tehran, Iran) according to the manufacturer's instructions. RNAs was treated with DNase I (Fermentas, Lithuania) to ensure the elimination of any genomic DNA contamination. Concentration, integration, and purity of RNA samples were determined by spectrometry and gel electrophoresis. Three micrograms of total RNA was used for cDNA synthesis with random hexamer and oligo (dT)18 primers through RevertAid™ Reverse Transcriptase (Fermantase, Canada) in total 20 μL reaction mixture.

Real-time PCR Analysis

Appropriate primers for IL-1, IL-8, TNF-α, transforming growth factor beta (TGF-β), vascular endothelial growth factor (VEGF), PPAR-γ and LDLR, and glyceraldehyde-3-phosphate dehydrogenase were designed (Table 1). Quantitative Real-time PCR was performed by LightCycler® 96 sequence detection systems (Roche Diagnostics, Rotkreuz, Switzerland) using 4 μL of 5× EVA GREEN I master mix (Salise Biodyne, Japan), 10 ng cDNA, 200 nM of each forward and reverse primers in final volume of 20 μL. PCR was performed through the following instruction: an initial denaturation at 95°C for 10 minutes, followed by 40 cycles of denaturation at 95°C for 10 seconds, annealing at 54–62.1°C for 15 seconds and extension at 72°C for 30 seconds. The specificity of PCR products was evaluated by 1.5% agarose gel electrophoresis and melting curve analysis. All experiments were performed at least in triplicate.

Sample Size

We used a randomized clinical trial sample size formula with type one (α) and type 2 errors (β) to be 0.05 and the power of 80% to calculate sample size. Based on a previous study, we used a standard deviation (SD) of 0.10-fold change and a difference in mean (d) of 0.11-fold change, considering TNF-α level as the key variable. According to the calculations, 21 individuals should be enrolled in each group. Assuming a dropout of 4 people per group, the final sample size was determined to be 25 people per group.

Statistical Methods

To determine whether the study variables were normally distributed or not, we used the Kolmogorov-Smirnov test. To detect differences in anthropometric measures, macro- and micro-nutrient intakes, gene expression related to inflammation, insulin, and lipid between 2 groups, we used Student’s t test to independent samples. Adjustment for changes in baseline values of biochemical variables, age and baseline BMI was performed by analysis of covariance (ANCOVA). Pearson Chi-square test was used for comparison of categorical variables. The P value of <0.05 were considered statistically significant. For all statistical analyses we used the Statistical Package for Social Science version 18 (SPSS Inc., Chicago, Illinois, USA).

Table 1. Specific Primers Used for Real-Time Quantitative PCR

Abbreviations: GAPDH, glyceraldehyde-3-Phosphate dehydrogenase; IL-1, interleukin-1; IL-8, interleukin-8; LDLR, oxidized low-density lipoprotein receptor; PPAR-γ, peroxisome proliferator-activated receptor gamma; TNF-α, tumor necrosis factor alpha; TGF-β, transforming growth factor beta; VEGF, vascular endothelial growth factor.
Borzabadi et al completed the trial (Figure 1).

Mean age, height, weight and BMI at week 0 and week 12 of the intervention were not different between 2 groups (Table 2).

Based on the 3-day dietary records obtained throughout the trial, we found no significant difference in mean macro- and micronutrient intakes between 2 groups (Data not shown).

Compared with the placebo, probiotic supplementation did not affect plasma NO (β 1.66; 95% CI, -1.31, 4.64; \( P = 0.26 \)) and GSH levels (β 9.90; 95% CI, -26.26, 46.06; \( P = 0.58 \)) (Table 3).

After the 12-week intervention, compared with the placebo, probiotic intake downregulated gene expression

\( ^\dagger \) "Outcome measures" refers to the change in values of measures of interest between baseline and week 12. β (difference in the mean outcomes measures between treatment groups [probiotic group = 1 and placebo group = 0]).

1 Obtained from ANCOVA (adjusted for baseline values of each biochemical variables, age and baseline BMI).

GSH, total glutathione; NO, nitric oxide.
of IL-1 (P = 0.03), IL-8 (P < 0.001) and TNF-α (P = 0.04) in peripheral blood mononuclear cells (PBMC of subjects with PD (Figure 2).

Probiotic supplementation upregulated TGF-β (P = 0.02) in PBMC of subjects with PD compared with the placebo (Figure 2). We did not observe any significant effect of probiotic supplementation on gene expression of VEGF in PBMC of patients with PD.

Probiotic intake upregulated PPAR-γ (P = 0.03) in PBMC of subjects with PD compared with the placebo (Figure 2). Probiotic supplementation did not affect gene expression of LDLR in PBMC of patients with PD was seen.

Discussion
In the current investigation, we evaluated the effects of probiotic supplementation on gene expression related to inflammation, insulin and lipid in individuals with PD. We found that probiotic supplementation for 12 weeks in populations with PD significantly improved gene expression of IL-1, IL-8, TNF-α, TGF-β and PPAR-γ, but did not affect VEGF and LDLR. To the best of our knowledge, this investigation is the first report of the effects of probiotic supplementation on biomarkers of inflammation and oxidative stress, and gene expression related to inflammation, insulin and lipid in populations with PD.

This study evidenced that probiotic supplementation to patients with PD for 12 weeks significantly downregulated gene expression levels of IL-1, IL-8 and TNF-α in PBMC compared with the placebo. Earlier, we have showed that probiotic supplementation for 12 weeks to patients with MS significantly decreased gene expression levels of IL-8 and TNF-α; however, it did not affect gene expression of IL-1. Furthermore, supplementation with Lactobacillus paracasei and L. reuteri in an animal model significantly decreased the expression of hepatic IL-1β, IL-6 and TNF-α through suppressing the mitogen-activated protein kinase (MAPK) and nuclear factor αB (NF-κB) signaling pathways. Gene expression of TNF-α, IL-1β and IL-6 was also up-regulated in intestinal mucositis tissues following the treatment with probiotics. In another study, Lactobacillus plantarum significantly downregulated gene expression of IL-8 and TNF-α in HT-29 cells at 6 hours as well as 24 hours. Therefore, due to their anti-inflammatory and anti-oxidative properties, probiotics may be useful to decrease the duration of neurological symptoms. Unlike, gene expression of TNF-α was not influenced with supplementation of overweight and obese people with 200 g/d yogurt enriched by L. acidophilus, Bifidobacterium BB12 and Lactobacillus casei for 8 weeks. Taking probiotic capsules for 8 weeks by patients with rheumatoid arthritis decreased hs-CRP, but did not influence NO levels. In addition, NO production was not changed in the groups treated with probiotic in herpes simplex virus type 1. Different study designs, lack of considering baseline levels of biochemical variables, different dosages and types of probiotic strains as well as duration of the intervention might provide some reasons for discrepant findings. Increased inflammatory markers are associated with increased microglia activation, which in turn would result in neurodegeneration through the release of free radicals, pro-inflammatory, immunomodulatory and anti-inflammatory cytokines. The dysfunctions in the immune system in terms of inflammatory cytokines production are intimately related to the nervous system alterations; therefore, controlling inflammatory markers may ameliorate the central inflammation and recovers the nervous system functions. Probiotic intake may decrease gene expression levels of inflammatory markers through modulating toll-like receptors, NF-κB and MAPK pathways. We found that probiotic supplementation for 12
weeks in people with PD upregulated gene expression of PPAR-γ in PBMC compared with the placebo, but did not affect gene expression of LDLR. Few animal and cell line studies have reported some effects of probiotics on gene expression levels of PPAR-γ and LDLR. In a study by Liu et al., it was seen that L. reuteri could improve the gut health of neonatal piglets by increasing colonic butyric acid levels and up-regulating the downstream molecules of butyric acid and PPAR-γ. In addition, L. casei supplementation in a rat model of acute liver failure significantly increased gene expression of PPAR-γ. Such beneficial effects of probiotic supplementation on signaling pathway related to insulin metabolism was not reported by others. For instance, gene expression of PPAR-γ was downregulated after the intake of probiotics in rat models. Dolatkhah et al. found that a 6-week probiotic supplementation to women with gestational diabetes mellitus did not influence insulin metabolism.

Abnormal signaling pathway related to insulin metabolism in people with PD may be correlated with extracellular events of relevance to neurodegeneration, inflammation and oxidative damage, which in turn is increasingly recognized as a main contributor to the pathogenesis of PD. Therefore, probiotics due to their beneficial effects on insulin metabolism may decrease metabolic events related to diabetes and cardiovascular diseases in patients with PD. PPAR-γ plays a key function in the regulation of metabolism, including regulating insulin sensitivity, mitochondrial biogenesis, and carbohydrate and lipid homeostasis. In addition, it was reported that PPAR-γ has potential beneficial effects in a number of neurological disorders, such as PD, Alzheimer’s disease and amyotrophic lateral sclerosis. Also, simultaneous targeting of dysfunctional pathways may underlie the potent neuroprotective activity displayed by PPAR-γ agonists. Probiotics intake may improve signaling pathway related to insulin metabolism by reducing cytokines and inhibiting the NF-kB pathway and gut microbiota-short chain fatty acids-hormone axis.

The current study had a number of strengths. Firstly, we focused on some interesting questions using a randomized, double-blind, placebo-controlled trial. The findings of improved gene expression related to inflammation and insulin in the probiotic group in our study are interesting, but need to be confirmed in a larger study. Another strength of the current study was the absence of dropout rate.

The current study had few limitations. In this study, due to funding limitations, we did not characterize the microbiota and thus could not establish whether probiotic intake over 12 weeks changed its composition. In addition, evaluating protein levels would have been more relevant. Unfortunately, we did not assess the effects of probiotic supplementation on protein levels.

Overall, probiotics supplementation for 12 weeks in PD patients significantly improved gene expression of IL-1, IL-8, TNF-α, TGF-β and PPAR-γ, but did not affect gene expression of VEGF and LDLR, and biomarkers of inflammation and oxidative stress. This suggests probiotic supplementation may confer advantageous therapeutic potential for people with PD. Further research is needed in other participants and for longer periods to determine the safety and beneficial effects of probiotic supplementation. Moreover, further studies should measure gene expression levels related to oxidative stress.
